Generation drawing notice delivery

The separate source38 lane replaces the Tiptoe-derived runtime geometry and removes its obsolete copies after source audit. The staged correction and earlier artifact statements below retain their original source-bound context. Clarabel/NetworkX notice delivery remains required.

Scope and ownership

This is the notices portion of WP11, implementing the accepted decision to retain Clarabel. The original notice change was independently approved before this drawing replay; this reconciled slice awaits its own review. The original base is `3f0df2a870806076820786994d4883dcec8e9e3`; historical M7 findings and frozen v4 `e0a779808174c64057fecfd062c948b8de8e5c1f` are provenance, not present-day artifact validation. Solver replacement, label placement and the kkumutpy port are separate work.

Clarabel is enabled by Linnet's `drawing` feature and consumed by Linnest, Linnet's Python bindings and the local Symbolica notebook host, including its `wasm` feature selection. Linnest's `ec_seed/coordinates.rs` contains the NetworkX-derived coordinate algorithm. These source and feature relationships, rather than searches for binary symbols, establish notice requirements.

At this base `crates/linnet-py` is an rlib, with no standalone wheel manifest or extension-module entrypoint. The historical standalone wheel cannot be rebuilt from this checkout. The in-repository wheel owner is `examples/notebooks/symbolica-host`, which owns both native and Pyodide builds. The separately maintained Symbolica Community distribution is outside this repository; its packager must collect the same notices when consuming these crates. No external repository was modified.

Delivery

The complete Clarabel license, including the University of Oxford copyright, comes from `vendor/clarabel/LICENSE.md`. The complete BSD notice and contributor credits come from `crates/linnest/layout/native/LICENSE.networkx`. Delivery copies are byte-identical to these sources. There is no separate Clarabel NOTICE file in the vendored source. The subsequent drawing replay removes the unused OGDF Typst plugin and its `LICENSE.ec-layout`; the local-only native reference engine remains. The Rust coordinate implementation still requires its NetworkX notice.

The Typst package now carries `LICENSE.networkx` beside `linnest.wasm` and declares BSD-3-Clause in its package license expression. The shared `crates/linnest/build_assets.rs` selector always includes root package licenses, so both Clinnet and GammaLoop extraction carry the same notice bytes alongside their embedded plugins. Existing MIT package licenses accompany Linnest and Kurvst too. Nix source filters, bundle installation and reconstructed drawing inputs retain these files. The root GammaLoop sdist explicitly includes them.

The local Symbolica host uses Maturin's `project.license-files` with `licenses/*`. This ships readable notices under wheel `.dist-info/licenses/` and advertises them through `License-File` metadata. Copies live in that existing conventional packaging location; no general license framework or runtime notice API was added.

Focused validation and limits

The structured receipt records commands, outcomes, source/output hashes and retained logs. Packaging regression coverage compiles the actual GammaLoop build script and extraction module in a small Cargo fixture, then compares extracted license and plugin bytes. A second fixture builds a wheel using the real host Python tree, pyproject and licenses with only a small substitute Rust module; it verifies license contents, metadata and RECORD hashes. This validates packaging, not the

full host runtime. Clinnet tests exercise production embedding and staging. The Nix WASM check compares licenses in its built bundle against their authoritative sources and validates the plugins. The original notice-only change did not regenerate WASM. The subsequent drawing replay rebuilds the bundles from its current sources. The source archive test also verifies all four package/license payloads. Targeted Clippy, changed-file Rust formatting, Python formatting and Typst compilation pass. The original workspace-wide `just fmt --check` recorded pre-existing formatting drift in `crates/linnet/src/permutation.rs`. The drawing replay passes the current workspace-wide formatting check. The modified Rust follows the current repository policy with no departures.

Real host metadata was inspected for native and Emscripten targets. The native fixture wheel was also passed through the production Pyodide compression script, which preserves its payload bytes. This is not a compiled Pyodide host wheel, nor a standalone Linnet wheel. Final integration must inspect the complete native/Pyodide host wheels and any restored standalone wheel, and verify the external Community packager includes both notices. Historical standalone `license-files = ["LICENSE", "licenses/*"]` can retain its owner: when replay restores that wheel, add Clarabel to its license directory and verify NetworkX against the authoritative source. Do not restore the obsolete standalone distribution as part of this notice-only change.

The original workspace and bookmark `generation-drawing-notices` are retained unchanged. The drawing replay preserves the common license selector and NetworkX/Clarabel files; see its receipt for current validation and deferred mark-engine work.

Staged drawing correction review

The bounded D1–D3 correction starts from the frozen staged candidate `817b5886a50276efea05ab860d22016e1fb0c203`. Both development sync recipes now copy all Kurvst root licenses, including retained Tiptoe attribution, alongside the shared mark source. The packaging regression upgrades an existing extracted bundle with its Tiptoe notice deliberately absent and compares every restored root notice byte for both recipes. The common production asset selector and authoritative Clarabel, NetworkX and Tiptoe license texts remain unchanged.

The Community WASM workflow installs its declared Rust toolchain, Python 3.13 and pinned Maturin before the packaging gate. An explicit online preparation step in the existing packaging test owner fetches the same two fixture manifests used by the offline build tests; preparation errors propagate before tests run. New shared-mark adapters use explicit module-scope type imports. The correction receipt records the exact changes, commands, results, identities and retained evidence. This correction awaits a new independent Astra review before integration.

Artifact certification remains narrower than source validation. The previous canonical Nix Kurvst WASM reproduces its committed bytes. The previous fresh Linnest WASM differs from the committed artifact in data and name sections, although executable/code sections match. Compile-time AHash RNG and source location changes are plausible causes, not a proven explanation. Final source, seed and source-location auditing and renewed bundle/runtime/SVG certification remain required; this correction performs no determinism refactor.

The committed Kurvst manual PDF still lacks the new mark-specification section, although the manual source compiles. Generated manual work belongs to source31 and the final documentation gate. Actual final repaired/compressed native, Pyodide and externally locked Community wheels still require installed behavior checks and inspection of METADATA License-File entries, notice bytes and RECORD hashes. Fixture wheels do not certify those distributions. Standalone Linnet packaging remains absent; restoration must carry its root and third-party licenses, including Tiptoe while this engine remains present.

Three historical frame-hash assertions and the seven inherited plus twenty new documentation-scope issues remain parent review items. Their expectations and unrelated scope digests are unchanged. No full-candidate, physics, final manual, distribution or WP3 approval is claimed here.
